WEEK 12 — PRODUCT CHARTER & PACKET

FINANCIAL EVIDENCE PASSPORT — PRODUCT CHARTER + PACKET

Version 0.1 · Week 12 · MONEY lens · 2026-11-01

Problem and exact user

A Mexican informal or thin-file micro-merchant has sales and expense records scattered across notebooks and chats. When asked to explain cash flow, organizing the evidence is slow and error-prone. First user: an adult market-stall merchant who can enter four fields on a smartphone. This is a hypothesis, not a claim of completed customer interviews.

Core promise and success definition

Before the module closes, a user can enter an income or expense, see totals recalculate, and export a CSV with their entries at a live URL. In authenticated mode, each account accesses only its own entries. A demo mode with fictional records works without credentials.

Product charter — what cannot change

We organize self-reported financial evidence; we do NOT verify income, assess creditworthiness, promise loan approval, or transmit documents to lenders. One core loop: record -> summarize -> export. User consent, data minimization and clarity outrank feature count. If an assumption fails, reduce scope rather than add AI theater.

Benchmark

Benchmark to investigate: QuickBooks' transaction categorization and reports for small businesses. This MVP differs by restricting the task to a Spanish-first, four-field self-reported ledger for Mexican thin-file merchants. Benchmark comparison is directional and requires research validation.

Three-year view

If the slice works, the product becomes a portable, user-controlled record of microbusiness cash flow. It may add opt-in evidence attachments and verification partnerships only after trust and consent are proven. Its long-term advantage would be traceability, not a black-box credit score.

Scope cut

NO credit scoring, AI-generated financial advice, bank integrations, document OCR, loan recommendations, admin dashboards, messaging or payments. No synthetic outputs are passed off as verified facts.

Architecture + stack

Security floor

Never commit .env.local; only publish Supabase anon key, never service role. Auth required for saved records. RLS enabled. Frontend and database enforce type/range/length constraints. Demo uses invented data labeled as such. No real personal data in seeds.

Test plan and acceptance criteria

1. Load page on mobile and desktop; all controls visible.

2. Demo displays three explicitly fictional rows and correct totals (1950 income, 240 expense, 1710 net).

3. Add valid income 100: income becomes 2050; CSV contains it.

4. Reject negative amount and 101-character note with visible errors.

5. After configuring Supabase, Google login creates a session; saved rows remain after reload; another user cannot read them (RLS).

6. Run `npm test`, `npm run build`; inspect deployment; document one real discovered bug, correction, and redeployment.

Milestone evidence status

Local unit tests: passed (3). Live URL, real domain, two deploys, five remote commits, OAuth integration test, persona screenshot walkthrough, video and shadow-clause compliance: NOT YET VERIFIED. The Crystal Ball Brief was not provided; its override conditions remain unknown.
